## HTML DOM

Prof. Dr. Jürgen Heym

Hochschule Hof

# HTML DOM

## W3C Document Object Model (DOM)

- Das Document Object Model (DOM) ist ein W3C-Standard.
- Das W3C-DOM definiert einen Standard für den Zugriff auf die Elemente eines Dokuments und deren Manipulation.

*"The W3C Document Object Model (DOM) is a platform and language-neutral interface that allows programs and scripts to dynamically access and update the content, structure, and style of a document."*

- Das DOM ist in drei Teile/Level aufgeteilt:
  - Core DOM      Standardmodell für strukturierte Dokumente
  - XML DOM      Standardmodell für XML-Dokumente
  - HTML DOM      Standardmodell für HTML-Dokumente
- Das DOM definiert die Objekte und Eigenschaften aller Elemente des Dokuments und Methode, diese zu manipulieren.

# HTML DOM

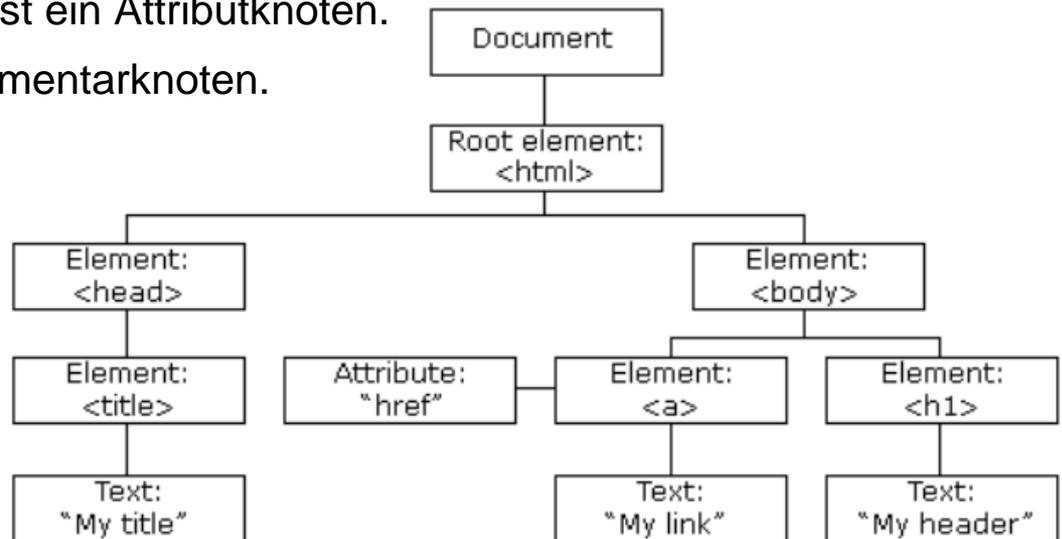

## HTML Document Object Model (DOM)

- Das HTML DOM ist
  - ein Standard-Objektmodell für HTML-Dokumente,
  - eine Standard-Programmierschnittstelle für HTML-Dokumente ,
  - Unabhängig von der Plattform und der Programmiersprache und
  - ein W3C-Standard.
- Das HTML DOM definiert die Objekte und Eigenschaften aller HTML-Elemente des Dokuments und Methoden, um auf diese zuzugreifen.
- Das HTML DOM ist ein Standard um HTML-Elemente zu lesen, ändern, hinzuzufügen und zu löschen.

# HTML DOM

## HTML DOM Knoten

- Im HTML DOM dreht sich alles um Knoten:
  - Das Gesamtdokument ist ein Dokumentenknoten.
  - Jedes HTML-Element ist ein Elementknoten.
  - Die Texte in HTML-Elementen sind Textknoten.
  - Jedes HTML-Attribute ist ein Attributknoten.
  - Kommentare sind Kommentarknoten.

# HTML DOM

## HTML DOM Beispiel

```
<html>  
  <head>  
    <title>DOM Tutorial</title>  
  </head>  
  <body>  
    <h1>DOM Lesson one</h1>  
    <p>Hello world!</p>  
  </body>  
</html>
```

- Der Wurzelknoten ist durch das html-Tag bestimmt.
- Alle anderen Knoten sind innerhalb des html-Tags.
- Der html-Knoten hat zwei Kinderknoten head und body.
- Der head-Knoten enthält einen title-Knoten.
- Der body-Knoten enthält einen h1- und einen p-Knoten.

# HTML DOM

## HTML DOM Beispiel

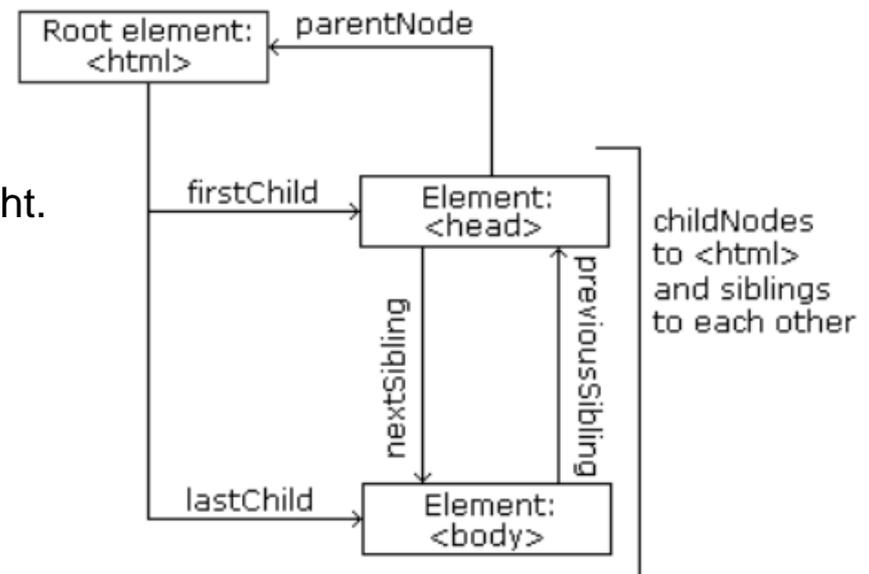

```
<html>
  <head>
    <title>DOM Tutorial</title>
  </head>
  <body>
    <h1>DOM Lesson one</h1>
    <p>Hello world!</p>
  </body>
</html>
```

- Ein Elementknoten enthält nie Text! Text wird immer in Textknoten abgelegt!
- In unserem Beispiel `<title>DOM Tutorial</title>` enthält der Elementknoten title einen Textknoten mit dem Wert "DOM Tutorial".
- "DOM Tutorial" ist nicht der Wert des title-Knotens!
- Im HTML DOM kann der Wert des Textknotens über die Eigenschaft `innerHTML` manipuliert werden.

# HTML DOM

## HTML DOM Knotenbaum

- Die Knoten in einem DOM-Knotenbaum haben eine hierarchische Beziehung zueinander.
- Man spricht von Eltern, Kindern und Geschwistern, um die Beziehung der Knoten zueinander zu beschreiben.
- Der Wurzelknoten wird auch als “top node” oder “root” bezeichnet.
- Jeder Knoten hat exakt einen Elternknoten, nur der Root-Knoten nicht.
- Jeder Knoten kann eine beliebige Anzahl von Kindknoten haben.
- Einen Knoten ohne Kindknoten bezeichnet man als Blatt (leaf).
- Geschwister sind Knoten mit gleichem Elternknoten.

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- HTML DOM Eigenschaften
  - `x.innerHTML` Wert des Textknoten innerhalb eines Elementes `x`.
  - `x.nodeName` Knotenname
  - `x.nodeValue` Wert oder Inhalt des Knotens
  - `x.parentNode` Elternknoten zu Element `x`
  - `x.childNodes` Kindknoten zu Element `x`
  - `x.attributes` Attribute des Elements `x`
  - `x.firstChild` Erster Kindknoten des Elements `x`
  - `x.lastChild` Letzter Kindknoten des Elements `x`

- HTML DOM Methoden
  - `x.getElementById(id)` Element mittels seiner *id* als Objekt auslesen.
  - `x.getElementsByTagName(name)` Alle Element einer bestimmten Tag-Klasse auslesen.
  - `x.appendChild(node)` Einen neuen Kindknoten einfügen.
  - `x.removeChild(node)` Einen Kindknoten entfernen.

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel: innerHTML-Eigenschaft

```
<html>
<body>

<p id="intro">Hello World!</p>

<script type="text/javascript">

    txt=document.getElementById("intro").innerHTML;

    document.write("<p>The text from the intro paragraph: " + txt + "</p>");

</script>

</body>
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel: Auslesen aller p-Tag-Inhalte

...

```
x=document.getElementsByTagName("p");
```

```
for (i=0;i<x.length;i++)  
{  
    document.write(x[i].innerHTML);  
    document.write("<br />");  
}
```

...

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel: Eigenschaften firstChild und lastChild

```
<html>
```

```
<body>
```

```
<p id="intro">Hello World!</p>
```

```
<script type="text/javascript">
```

```
    x=document.getElementById("intro");
```

```
    document.write(x.firstChild.nodeValue);
```

```
</script>
```

```
</body>
```

```
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Spezielle Knoten
  - **document.documentElement**  
referenziert den Root-Knoten des Dokuments.
  - **document.body**  
referenziert das body-Tag eines Dokuments.

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Eigenschaften aller Knoten
  - Im HTML DOM ist jeder Knoten ein Objekt.
  - Objekte haben Methoden und Eigenschaften, die mittels JavaScript manipuliert werden können.
  - Drei wichtige Eigenschaften jedes Knotens sind:
    - **nodeName**
    - **nodeValue**
    - **nodeType**

- nodeName-Eigenschaft
  - Die nodeName-Eigenschaft bestimmt den Namen des Knotens.
  - Der nodeName ist nur lesbar (read-only).
  - Der nodeName eines Elements ist identisch zum Tag-Namen.
  - Der nodeName eines Attributs ist identisch zum Attributnamen.
  - Der nodeName eines Textknotens ist immer #text.
  - Der nodeName des Gesamtdokuments ist immer #document.

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- nodeValue-Eigenschaft
  - Die nodeValue-Eigenschaft bestimmt den Inhalt des Knotens.
  - Die nodeValue-Eigenschaft ist für Elementknoten nicht definiert.
  - Die nodeValue-Eigenschaft eines Textknotens ist der Text selbst.
  - Die nodeValue-Eigenschaft für Attributknoten ist der Attributwert.

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- nodeType-Eigenschaft
  - Die nodeType-Eigenschaft kann nur gelesen werden und bestimmt den Knotentyp.

Element type	NodeType
Element	1
Attribute	2
Text	3
Comment	8
Document	9

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel
  - Änderung der Hintergrundfarbe des body-Tags.

```
<html>  
<body>  
  
  <script type="text/javascript">  
    document.body.backgroundColor="lavender";  
  </script>  
  
</body>  
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel
  - Änderung des Inhalts des Elementes „p1“.

```
<html>
```

```
<body>
```

```
<p id="p1">Hello World!</p>
```

```
<script type="text/javascript">
```

```
    document.getElementById("p1").innerHTML="New text!";
```

```
</script>
```

```
</body>
```

```
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel
  - Änderung einer Eigenschaft bei Mausklick.

```
<html>
```

```
<body>
```

```
<input type="button"  
      onclick="document.body.bgColor='lavender' ;"  
      value="Change background color" />
```

```
</body>
```

```
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel
  - Änderung des Inhalts des Elementes „p1“ über sein style-Objekt.

```
<html>
<head>
<script type="text/javascript">
function ChangeBackground()
{
    document.body.style.backgroundColor="lavender";
}
</script>
</head>

<body>
<input type="button" onclick="ChangeBackground() "
    value="Change background color" />
</body>
</html>
```

# HTML DOM

## HTML DOM Eigenschaften und Methoden

- Beispiel
  - Änderung von Font und Farbe es Elements „p1“.

```
<html>
<head>
<script type="text/javascript">
function ChangeStyle()
{
    document.getElementById("p1").style.color="blue";
    document.getElementById("p1").style.fontFamily="Arial";
}
</script>
</head>

<body>
<p id="p1">Hello world!</p>
<input type="button" onclick="ChangeStyle() "
    value="Change style" />
</body>
</html>
```

# HTML DOM

## HTML DOM Ereignisse (events)

- Ereignisse (events)

Jedes Element einer Webseite hat bestimmte Möglichkeiten Ereignisse an JavaScript-Funktionen weiterzuleiten:

- Mausklick
- Tastendruck
- Laden einer neuen Seite oder eines Bildes.
- Bewegung der Maus über einen Hotspot.
- Auswahl eines Eingabefeldes.
- Abschicken eines Formulars.

Beispiel: `E-mail: <input type="text" id="email" onchange="checkEmail()" />`

Referenz: Siehe Vorlesung “Javascript 1”.

# HTML DOM

## Beispiele

- Beispiel

Wie viele Anker enthält ein Dokument? Antwort: Nur Anker mit name-Attribut werden gezählt!

```
<html>
<body>
<a name="html">HTML Tutorial</a><br />
<a name="css">CSS Tutorial</a><br />
<a name="xml">XML Tutorial</a><br />
<a href="/js/">JavaScript Tutorial</a>

<p>Number of anchors:
<script type="text/javascript">
    document.write(document.anchors.length) ;
</script>
</p>
</body>
</html>
```

# HTML DOM

## Beispiele

- Beispiel

Rückgabe der Eigenschaft innerHTML des ersten Ankers.

```
<html>
<body>

<a id="html">HTML Tutorial</a><br />
<a id="css">CSS Tutorial</a><br />
<a id="xml">XML Tutorial</a>

<p>innerHTML of the first anchor:
<script type="text/javascript">
    document.write (document.anchors [0] .innerHTML) ;
</script>
</p>

</body>
</html>
```

# HTML DOM

## Beispiele

- Beispiel

Wie viele Formulare enthält das aktuelle Dokument?

```
<html>
<body>

<form name="Form1"></form>
<form name="Form2"></form>
<form></form>

<p>Number of forms:
<script type="text/javascript">
    document.write (document.forms.length) ;
</script>
</p>

</body>
</html>
```

# HTML DOM

## Beispiele

- Beispiel

Wie heißt das erste Formular?

```
<html>
<body>

<form name="Form1"></form>
<form name="Form2"></form>
<form></form>

<p>Name of first form:
<script type="text/javascript">
document.write (document.forms [0] .name) ;
</script>
</p>

</body>
</html>
```

# HTML DOM

## Beispiele

- Beispiel

Wie viele Bilder sind im dokument referenziert?

```
<html>
<body>

<p>Number of images:
<script type="text/javascript">
    document.write(document.images.length) ;
</script>
</p>

</body>
</html>
```

**siehe:** [http://www.w3schools.com/jsref/tryit.asp?filename=tryjsref\\_doc\\_images](http://www.w3schools.com/jsref/tryit.asp?filename=tryjsref_doc_images)

# HTML DOM

## Beispiele

- Beispiel

Welche Cookies sind gesetzt?

```
<html>
```

```
<body>
```

Cookies associated with this document:

```
<script type="text/javascript">  
    document.write(document.cookie) ;  
</script>
```

```
</body>
```

```
</html>
```

# HTML DOM

## Beispiele

- Beispiel

Öffnen eines neuen Fensters und einfügen von Text in das neue HTML DOM.

```
<html>
<body>

<script type="text/javascript">
    var w=window.open();
    w.document.open();
    w.document.write("<h1>Hello World!</h1>");
    w.document.close();
</script>

</body>
</html>
```

# HTML DOM

# Internettechniken

## JavaScript Teil 1

Prof. Dr. Jürgen Heym

Hochschule Hof

# JavaScript

## Einleitung

- JavaScript ist eine der wichtigsten Script-Sprachen im Web.
- JavaScript wird auf unzähligen Webseiten für verschiedene Aufgaben eingesetzt:
  - Dynamische Funktionen
  - Formularvalidierung
  - Kommunikation zu einem Server

# JavaScript

## Einleitung

### Was ist JavaScript?

- JavaScript wurde entwickelt, um HTML-Seiten Interaktivität hinzuzufügen.
- JavaScript ist eine Skriptsprache.
- JavaScript ist eine Leichtgewicht-Programmiersprache.
- JavaScript wird in HTML eingebettet.
- JavaScript wird von einem Interpreter ausgeführt, es gibt keinen JavaScript-Compiler.
- JavaScript ist lizenzfrei und kann von jedem eingesetzt werden.

# JavaScript

## Einleitung

JavaScript == ECMAScript

- JavaScript ist eine Implementation des ECMA Skriptsprachen Standards.
- *ECMA == European Computer Manufacturers Association.*
- JavaScript entspricht dem Standard ECMA-262.
- JavaScript wurde von Brendan Eich in Netscape Navigator 2.0 erstmals eingeführt und ist seit 1996 in allen Browsern verfügbar.
- Der offizielle ECMAScript-262 Standard wurde 1997 verabschiedet und 1998 als ISO 16262 übernommen.
- JavaScript befindet sich immer noch in der Weiterentwicklung.

# JavaScript

## Beispiele

### Beispiel 1: Text in ein HTML-Dokument schreiben

```
<html>
<body>

<h1>My First Web Page</h1>

  <script type="text/javascript">
    document.write("<p>" + Date() + "</p>");
  </script>

</body>
</html>
```

# JavaScript

## Beispiele

### Beispiel 2: HTML-Elemente überschreiben

```
<html>  
<body>
```

```
<h1>My First Web Page</h1>
```

```
<p id="demo"></p>
```

```
<script type="text/javascript">  
    document.getElementById("demo").innerHTML=Date();  
</script>
```

```
</body>  
</html>
```

# JavaScript

## Grundlagen

Manche Browser unterstützen kein JavaScript!

- Diese Browser stellen JavaScript als Seiteninhalt dar!
- JavaScript sollte daher in HTML-Kommentarzeichen eingebettet werden. Dies ist Teil des JavaScript-Standards.
- Beispiel:

```
...  
    <script type="text/javascript">  
    <!--  
        document.getElementById("demo").innerHTML=Date();  
    //-->  
    </script>  
...
```

Der Doppelslash in der vorletzten Zeile ist ein JavaScript-Kommentar, der verhindert, dass „-->“ ausgeführt wird.

# JavaScript

## Grundlagen

JavaScript kann an unterschiedlichen Stellen stehen:

1. im Header des HTML-Dokuments oder
2. Im Body des HTML-Dokuments .

Wir können eine unbegrenzte Anzahl JavaScripts in einem Dokument ausführen lassen.

JavaScripte können im Header und im Body oder in beiden stehen.

Häufig findet man JavaScript im Header oder ganz am Ende eines Dokuments im Body-Bereich.

### Beispiel 3: HTML-Elemente überschreiben

```
<html>

<head>
  <script type="text/javascript">
    function displayDate()
    {
      document.getElementById("demo").innerHTML=Date();
    }
  </script>
</head>

<body>
<h1>My First Web Page</h1>
<p id="demo"></p>

<button type="button" onclick="displayDate()">Display Date</button>
</body>

</html>
```

# JavaScript

## Grundlagen

JavaScript kann auch in externe Dateien ausgelagert werden:

```
<html>
<head>
...
<script type="text/javascript" src="xxx.js"></script>
...
</head>
<body>
...
</body>
</html>
```

# JavaScript

## Grundlagen --- Statements

- JavaScript berücksichtigt Groß-/Kleinschreibung.
- Jedes JavaScript-Statement ist ein Kommando für den Browser.
- JavaScript-Statements enden normalerweise mit einem Strichpunkt, müssen aber nicht!
- Ein JavaScript ist eine Sequenz von JavaScript-Statements.
- Kommentare
  - einzeiliger Kommentar: `// ... ..`
  - Mehrzeilige Kommentare: `/* ... .. */`

# JavaScript

## Grundlagen --- Variablen

- JavaScript-Variablen
  - berücksichtigen Groß-/Kleinschreibung und
  - Müssen mit einem Buchstaben oder Unterstrich beginnen.

```
<html>
<body>
<script type="text/javascript">
    var firstname;
    firstname="Hege";
    document.write(firstname);
</script>
</body>
</html>
```

# JavaScript

## Grundlagen --- Variablen

- JavaScript-Variablendeklaration
  - Schlüsselwort: var
  - mit und ohne Wertzuweisung

```
var firstname;
```

```
var x=5;
```

```
var carname="volvo";
```

- Es gibt in JavaScript lokale globale Variablen
  - Lokale Variablen sind nur innerhalb einer Funktion gültig und werden am Ende der Funktion ungültig.
  - Globale Variablen sind funktionsübergreifend gültig und werden am Ende der Seitenverarbeitung ungültig.
  - Globale Variablen werden ohne das Schlüsselwort var deklariert.

```
var firstname;           // lokale Variable
x=5;                    // globale Variablen
carname="volvo";
```

# JavaScript

## Grundlagen --- Arithmetische Operatoren

- Mit der Vorbelegung  $y=5$  gilt:

Operator	Description	Example	Result	
+	Addition	$x=y+2$	$x=7$	$y=5$
-	Subtraction	$x=y-2$	$x=3$	$y=5$
*	Multiplication	$x=y*2$	$x=10$	$y=5$
/	Division	$x=y/2$	$x=2.5$	$y=5$
%	Modulus (division remainder)	$x=y\%2$	$x=1$	$y=5$
++	Increment	$x=++y$	$x=6$	$y=6$
		$x=y++$	$x=5$	$y=6$
--	Decrement	$x=--y$	$x=4$	$y=4$
		$x=y--$	$x=5$	$y=4$

# JavaScript

## Grundlagen --- Zuweisungsoperatoren

- Mit der Vorbelegung  $x=10$  und  $y=5$  gilt:

Operator	Example	Same As	Result
=	$x=y$		$x=5$
+=	$x+=y$	$x=x+y$	$x=15$
-=	$x-=y$	$x=x-y$	$x=5$
*=	$x*=y$	$x=x*y$	$x=50$
/=	$x/=y$	$x=x/y$	$x=2$
%=	$x%=y$	$x=x\%y$	$x=0$

# JavaScript

## Grundlagen --- Zeichenketten

- Verkettung von Zeichenketten

```
txt1 = "What a very";  
txt2 = "nice day";  
txt3 = txt1 + " " + txt2;  
document.write(txt3);
```

# JavaScript

## Grundlagen --- Vergleichsoperatoren

- Mit der Vorbelegung `x=5` gilt:

Operator	Description	Example
<code>==</code>	is equal to	<code>x==8</code> is false <code>x==5</code> is true
<code>===</code>	is exactly equal to (value and type)	<code>x===5</code> is true <code>x==="5"</code> is false
<code>!=</code>	is not equal	<code>x!=8</code> is true
<code>&gt;</code>	is greater than	<code>x&gt;8</code> is false
<code>&lt;</code>	is less than	<code>x&lt;8</code> is true
<code>&gt;=</code>	is greater than or equal to	<code>x&gt;=8</code> is false
<code>&lt;=</code>	is less than or equal to	<code>x&lt;=8</code> is true

# JavaScript

## Grundlagen --- Logische Operatoren

- Mit der Vorbelegung  $x=6$  und  $y=3$  gilt:

Operator	Description	Example
&&	and	$(x < 10 \ \&\& \ y > 1)$ is true
	or	$(x == 5 \    \ y == 5)$ is false
!	not	$!(x == y)$ is true

- Bedingte Zuweisung

```
variablename = (condition) ? value1 : value2
```

Beispiel:

```
greeting = (visitor=="PRES") ? "Dear President " : "Dear ";
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Bedingte Verzweigung

```
if (condition)  
{  
    code to be executed if condition is true  
}
```

- Beispiel

```
<script type="text/javascript">  
    // Write a "Good morning" greeting if the time is less than 10  
    var d=new Date();  
    var time=d.getHours();  
  
    if (time<10)  
    {  
        document.write("<b>Good morning</b>");  
    }  
</script>
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Bedingte Verzweigung 2

```
if (condition)
{
    code to be executed if condition is true
}
else
{
    code to be executed if condition is not true
}
```

- Beispiel

```
if (time<10)
{    document.write("<b>Good morning!</b>");    }
else
{    document.write("<b>Good day!</b>");    }
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Bedingte Verzweigung 3

```
if (condition1)
{
  code to be executed if condition1 is true
}
else if (condition2)
{
  code to be executed if condition2 is true
}
else
{
  code to be executed if neither condition1 nor condition2 is true
}
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Beispiel mit Zufallslink

```
<html>
<body>

<script type="text/javascript">
  var r=Math.random();
  if (r>0.5)
  {
    document.write("<a href='http://www.fh-hof.de'>FH</a>");
  }
  else
  {
    document.write("<a href='http://www.uni-bt.de'>Uni BT</a>");
  }
</script>

</body>
</html>
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Switch-Statement

```
switch(n)
{
case 1:
    execute code block 1
    break;
case 2:
    execute code block 2
    break;
default:
    code to be executed if n is different from case 1 and 2
}
```

# JavaScript

## Grundlagen --- Bedingte Verzweigung

- Switch-Statement

```
<script type="text/javascript">
  var d=new Date();
  var theDay=d.getDay();
  switch (theDay)
  {
    case 5: document.write("Freitag");
            break;
    case 6: document.write("Samstag");
            break;
    case 0: document.write("Sonntag");
            break;
    default:
            document.write("Bald ist Wochenende!");
  }
</script>
```

# JavaScript

## Grundlagen --- PopUp-Boxen

- Alert-Popup

```
<html>
<head>
<script type="text/javascript">
function show_alert()
{
    alert("I am an alert box" + '\n' + "with line break!");
}
</script>
</head>
<body>

<input type="button" onclick="show_alert()" value="Show alert box" />

</body>
</html>
```

# JavaScript

## Grundlagen --- PopUp-Boxen

- Confirm-Popup

```
<html>
<head>
<script type="text/javascript">
function show_confirm()
{
    var r=confirm("Knopf drücken!");
    if (r==true){ alert("OK!"); }
    else { alert("Cancel!"); }
}
</script>
</head>
<body>

<input type="button" onclick="show_confirm()" value="Bestätigung" />

</body>
</html>
```

# JavaScript

## Grundlagen --- PopUp-Boxen

- Prompt-Popup

```
<html>
<head>
<script type="text/javascript">
function show_prompt()
{
var name=prompt("Please enter your name", "Harry Potter");
if (name!=null && name!="")
    {
    document.write("Hello " + name + "! How are you today?");
    }
}
</script>
</head>
<body>

<input type="button" onclick="show_prompt()" value="Show prompt box" />

</body>
</html>
```

# JavaScript

## Grundlagen --- Funktionen

- Syntax

```
function functionname(var1,var2,...,varX)
{
    Funktionsblock
}
```

- Beispiel

```
...
<script type="text/javascript">
    function product(a,b)
    {
        return a*b;
    }
</script>
</head>
<body>
    <script type="text/javascript">
        document.write(product(4,3));
    </script>
...

```

### Beispiel

```
<html>
<head>
<script type="text/javascript">
    function myfunc(txt) {alert (txt);}
</script>
</head>
<body>

<form>
onclick="myfunc('Hello')" value="Call function">
</form>
```

<p>By pressing the button above, a function will be called with "Hello" as a parameter. The function will alert the parameter.</p>

```
</body>
</html>
```

- For-Loop

```
for (variable=start;variable<=end;variable=variable+increment)
{
  code to be executed
}
```

- Beispiel

```
...
<script type="text/javascript">
var i=0;
for (i=0;i<=5;i++)
{
    document.write("The number is " + i);
    document.write("<br />");
}
</script>
...
```

# JavaScript

## Grundlagen --- Schleifen

- While-Loop

```
while (variable<=endvalue)
{
    code to be executed
}
```

- Beispiel

```
...
<script type="text/javascript">
var i=0;
while (i<=5)
    {
        document.write("The number is " + i);
        document.write("<br />");
        i++;
    }
</script>
...
```

# JavaScript

## Grundlagen --- Schleifen

- Do-While-Loop

```
do
  {
    code to be executed
  }
while (variable <= endvalue);
```

- Beispiel

```
...
<script type="text/javascript">
var i=0;
do
  {
    document.write("The number is " + i);
    document.write("<br />");
    i++;
  }
while (i<=5);
</script>
```

- Schleifen unterbrechen

```
<html>
<body>
<script type="text/javascript">
var i=0;
for (i=0;i<=10;i++)
  {
    if (i==3)
      {
        break;
      }
    document.write("The number is " + i);
    document.write("<br />");
  }
</script>
</body>
</html>
```

- Schleifen beim nächsten Wert fortsetzen

```
<html>
<body>
<script type="text/javascript">
var i=0
for (i=0;i<=10;i++)
  {
    if (i==3)
      {
        continue;
      }
    document.write("The number is " + i);
    document.write("<br />");
  }
</script>
</body>
</html>
```

- For-In-Schleife

Die for-in-Schleife iteriert über die Eigenschaften eines Objektes.

```
for (variable in object)
{
  code to be executed
}
```

- Beispiel

```
var person={fname:"John",lname:"Doe",age:25};

for (x in person)
{
  document.write(person[x] + " ");
}
```

# JavaScript

## Grundlagen --- Ereignisse

- Ereignisse können von JavaScript detektiert werden.

```
<html>
<head>
<script type="text/javascript">
function displayDate()
{
    document.getElementById("demo").innerHTML=Date();
}
</script>
</head>

<body>
<h1>My First Web Page</h1>
<p id="demo"></p>
<button type="button" onclick="displayDate()">Display Date</button>
</body>
</html>
```

# JavaScript

## Grundlagen --- Ereignisse

- Ereignisse sind
  - Mausklicks
  - Webseite oder Bild laden
  - Mausbewegung über einen Hotspot der Seite
  - Auswahl eines Eingabefeldes in einem Formular
  - Abschicken eines Formulars
  - Tastendruck
- Trigger
  - onLoad, onUnload
  - onFocus, onBlur, onChange
  - onSubmit
  - onMouseover

# Debugging JavaScript

Joe Oakes

[jxo19@psu.edu](mailto:jxo19@psu.edu)

# Why Perform Debugging

- Helps you understand the coding syntax
- Helps you understand the code logic better
- Helps you understand the code and follow code pathways
- Helps you find bugs and logic errors
- Makes you a better programmer

```
<!DOCTYPE html>
```

```
<html>
```

```
<head></head>
```

```
<body>
```

```
  <a id= "add" onclick="addTwoNumbers()" href="#test">add two numbers</a>
```

```
<script>
```

```
  function addTwoNumbers(var1, var2){
```

```
    return var1+var2;
```

```
  }
```

```
</script>
```

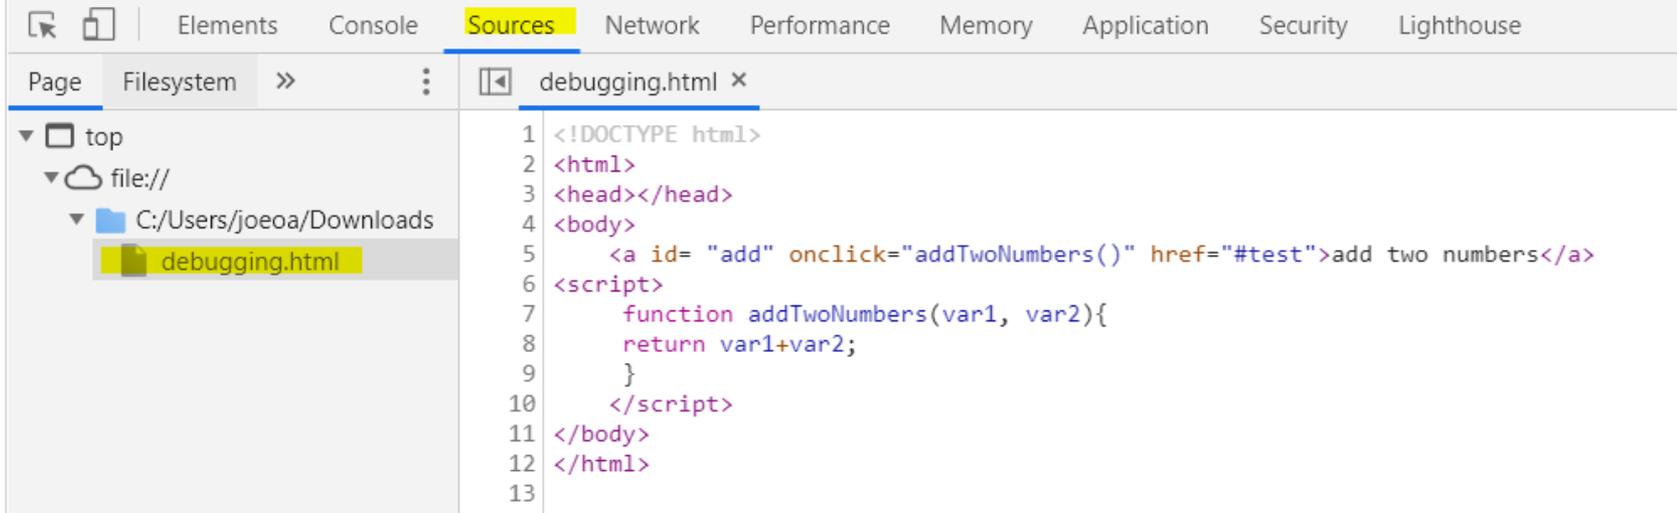

```
</body>
```

```
</html>
```

Source HTML and JavaScript code you can use to cut and paste into an editor

Open the Browser's Developer Tools  
Control+Shift+I

[add two numbers](#)

The screenshot shows a browser window with the developer tools open. The 'Sources' tab is selected, displaying the source code of a file named 'debugging.html'. The code is as follows:

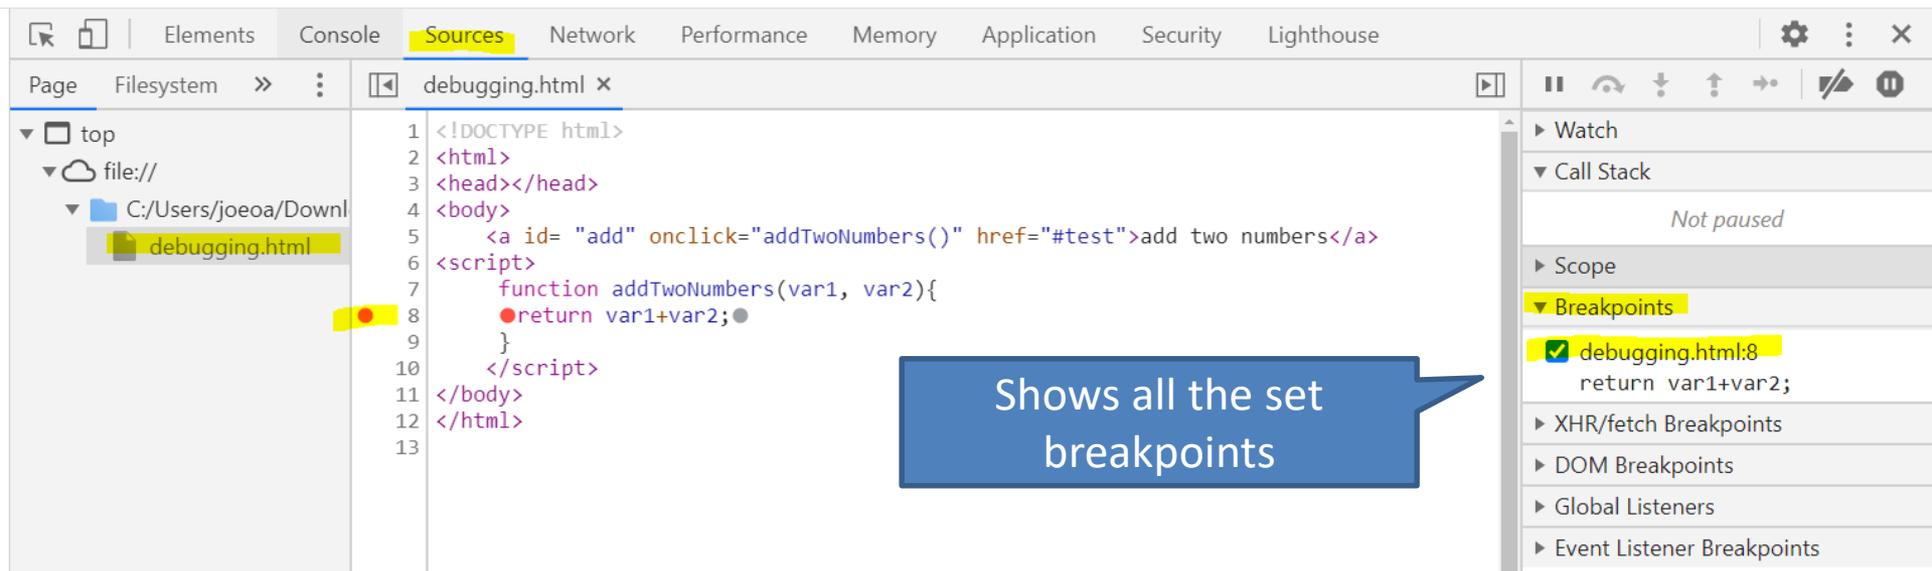

```
1 <!DOCTYPE html>
2 <html>
3 <head></head>
4 <body>
5   <a id= "add" onclick="addTwoNumbers()" href="#test">add two numbers</a>
6 <script>
7   function addTwoNumbers(var1, var2){
8     return var1+var2;
9   }
10  </script>
11 </body>
12 </html>
13
```

# JavaScript Debugging Details

- **Breakpoints:** Set code execution points to stop
- **Instruction Pointer:** Current location in the code
- **Step over:** Step over a function it still executes
- **Step into:** Step into a function to trace through it
- **Step out:** Step out of a function
- **Call stack:** show what function calls have been push onto the stack
- **Watch:** watch variables/objects in the memory
- **Scope:** show variables in scope

# Debugging Details: Breakpoint

- Breakpoint: Set code execution points to stop
  - Set the location by clicking on the gutter area
  - This can be toggled by clicking it again

# Debugging Details: Breakpoint

- Reload the page and select the link
- Notice var1 and var2 are undefined variables

The screenshot shows the Chrome DevTools interface. The 'Sources' panel is open, displaying the code for 'debugging.html'. A red dot indicates a breakpoint is set at line 8, which is the return statement of the 'addTwoNumbers' function. The function signature is 'function addTwoNumbers(var1, var2)'. The console shows 'var1 = undefined, var2 = undefined'. The call stack on the right shows the function was called from an 'onclick' event on a link. The scope panel shows 'this' as 'Window' and 'var1' and 'var2' as 'undefined'.

var1 and var2 are undefined

```
<!DOCTYPE html>

# Debugging Details: Conditional Breakpoint

- Conditional Breakpoint hit

The screenshot shows a browser's developer console with a code editor on the left and a debugging sidebar on the right. The code editor displays the following HTML and JavaScript code:

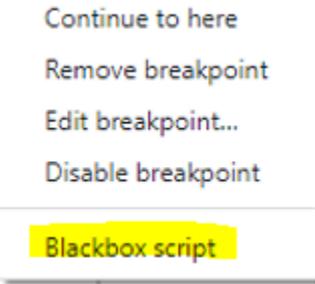

```
1 <!DOCTYPE html>
2 <html>
3 <head></head>
4 <body>
5   <a id= "add" onclick="addTwoNumbers(2, 4)" href="#test">add two numbers</a>
6 <script>
7   function addTwoNumbers(var1, var2){ var1 = 2, var2 = 4
8   return var3 = var1+var2;
9   }
10 </script>
11 </body>
12 </html>
13
```

The line `return var3 = var1+var2;` on line 8 is highlighted in yellow, indicating a breakpoint hit. The debugging sidebar on the right shows the following information:

- Paused on breakpoint** (highlighted in yellow)
- Watch**
- Call Stack**
  - addTwoNumbers debugging.html:8
  - onclick VM847 debugging.html:5
- Scope**
- Local**
  - this: Window
  - var1: 2
  - var2: 4
- Global** Window
- Breakpoints**
  - debugging.html:8 return var3 = var1+var2;

# Debugging Details: Blackboxing

- Blackbox
  - When you don't know the internal workings of a given system
  - Blackboxing gives you a way to denote library (or other abstraction) code so that the debugger can route around it.

Continue to here  
Remove breakpoint  
Edit breakpoint...  
Disable breakpoint  
**Blackbox script**

## Framework Blackboxing

---

Debugger will skip through the scripts and will not stop on exceptions thrown by them.

# Debugging Details: Controls

- Debugger Controls

- **Resume:** Continue to the next breakpoint
- **Step over:** Step over a function it still executes
- **Step into:** Step into a function to step through it
- **Step out:** Step out of a function
- **Step:** Step to the next line
- **Deactivate Breakpoints**
- **Pause on exceptions**

# Debugging Details: Examine Values

- You can use the Console to examine or change values

The screenshot shows the Chrome DevTools interface with a breakpoint set on line 8 of a JavaScript function. The function is named `addTwoNumbers` and takes two arguments, `var1` and `var2`. The breakpoint is located at the `return` statement: `return var3 = var1+var2;`. A callout box points to this line, stating: "This line has not been executed so var3 is not defined yet".

The right-hand side of the interface shows the "Paused on breakpoint" panel. The "Call Stack" shows the current function call: `addTwoNumbers debugging.html:8`. The "Scope" panel shows the local variables: `this: Window`, `var1: 2`, and `var2: 4`. The "Breakpoints" panel shows the current breakpoint location: `VM45 debugging.html:5`.

The bottom of the screenshot shows the Console panel with the following error message:

```
> var3
Uncaught ReferenceError: var3 is not defined
    at eval (eval at addTwoNumbers (debugging.html:1), <anonymous>:1:1)
    at addTwoNumbers (debugging.html:8)
    at HTMLAnchorElement.onclick (VM45 debugging.html:5)
```

# Debugging Details: Examine Values

- Use the Step icon to execute the line
- Clear the Console using the icon

The screenshot shows the Chrome DevTools interface with the Sources panel open to a file named 'debugging.html'. The code is as follows:

```
1 <!DOCTYPE html>
2 <html>
3 <head></head>
4 <body>
5   <a id= "add" onclick="addTwoNumbers(2, 4)" href="#test">add two numbers</a>
6 <script>
7   function addTwoNumbers(var1, var2){ var1 = 2, var2 = 4
8   return var3 = var1+var2;
9   }
10 </script>
11 </body>
12 </html>
13
```

The function call on line 5 and the function definition on lines 7-9 are highlighted. The return statement on line 8 is also highlighted. The status bar at the bottom indicates 'Line 8, Column 27' and 'Coverage: n/a'.

The right-hand sidebar shows the 'Debugger paused' state. The 'Call Stack' panel shows the current call to 'addTwoNumbers' at 'debugging.html:8'. The 'Scope' panel shows the 'Local' scope with 'Return value: 6', 'this: Window', 'var1: 2', and 'var2: 4'. The 'Global' scope is also visible, showing 'Window'.

The bottom console shows the command '> var3' and the result '< 6'.

> var3

< 6

# Debugging Details: Watch

- You can use the Watch feature to watch a variable
- Click on the + to select the variable to watch

The screenshot displays a web browser's developer console with the following components:

- Code Editor:** Shows HTML and JavaScript code. The JavaScript function `addTwoNumbers` is paused at line 8: `return var3 = var1+var2;`. The current values of `var1 = 2` and `var2 = 4` are visible above the line.
- Debugger Panel:** Shows the current state of the debugger, including the paused function `addTwoNumbers` and the `onclick` event.
- Watch Panel:** Displays the variable `var3` with a value of `6`. A plus sign (+) is visible next to the Watch panel header.
- Call Stack:** Shows the call stack with `addTwoNumbers` at `debugging.html:8` and `onclick` at `VM45 debugging.html:5`.
- Scope Panel:** Shows the local scope with `Return value: 6`, `this: Window`, `var1: 2`, and `var2: 4`.
- Console Panel:** Shows the command `> var3` and the output `< 6`.

Use the + to add an expression

# Debugging Details: Assignment

- You can change the value of a variable in the console

Make sure to refresh

Using the assignment operator changed the value from 6 to 7

```
1 <!DOCTYPE html>
2 <html>

# Debugging Details: External File

- Select Page -> Filesystem -> filename.js
- Set your breakpoints in the gutter area

# Debugging Details: Breakpoints

- You have many breakpoints set
  - You can manage them in the Breakpoints area

The screenshot shows a web browser's developer tools interface. The main pane displays the source code for 'filename.js' with two functions: 'addTwoNumbers' and 'subTwoNumbers'. Both functions have a red dot breakpoint on their respective 'return' statements. The right-hand sidebar contains several panels: 'Watch' (showing 'total: <not available>'), 'Call Stack' (showing 'Not paused'), 'Scope' (showing 'Not paused'), and 'Breakpoints'. The 'Breakpoints' panel is expanded and shows two active breakpoints: 'filename.js:2' and 'filename.js:5', both with checkboxes checked and the corresponding code lines highlighted in yellow.

```
1 function addTwoNumbers(var1, var2){  
2   return var3 = var1+var2; ●  
3 }  
4 function subTwoNumbers(var1, var2){  
5   return var3 = var1-var2; ●  
6 }  
7
```

▼ Watch + ↻

▼ Scope  
Not paused

▼ Breakpoints

- filename.js:2  
return var3 = var1+var2;
- filename.js:5  
return var3 = var1-var2;

# Debugging Details: Breakpoints

- When the breakpoint is hit notice the area will turn yellow

The screenshot displays a web browser's developer console with a JavaScript file named 'filename.js' open. The code in the editor is as follows:

```
1 function addTwoNumbers(var1, var2){  
2   return var3 = var1+var2;  
3 }  
4 function subTwoNumbers(var1, var2){ var1 = 4, var2 = 4  
5   return var3 = var1-var2;  
6 }  
7
```

The breakpoint on line 5 of the `subTwoNumbers` function is active, and the code is paused at that line. The right-hand sidebar shows the following details:

- Paused on breakpoint**
- Call Stack**:
  - subTwoNumbers filename.js:5
  - onclick VM188 debugging.html:8
- Scope**
- Breakpoints**:
  - filename.js:2  
return var3 = var1+var2;
  - filename.js:5  
return var3 = var1-var2;

A blue callout box with the text "Breakpoint hit" points to the breakpoint in the sidebar.

# JavaScript: Variable Scope

- **Variable scope:** what is the value of a specific variable name at the current line of code being executed
- JavaScript allows for both **global** and **local** scope of a variable
- **Global:** defined in the main JavaScript
- **Local:** defined in a function a new variable is created in memory
- Outside of the function referencing global

The image shows a code editor on the left and a debugger sidebar on the right. The code editor contains the following JavaScript code:

```
1 function addTwoNumbers(var1, var2){ var1 = 2, var2 = 4
2 return var3 = var1+var2;
3 }
```

The debugger sidebar on the right is titled "Paused on breakpoint" and shows the following information:

- ▶ Watch
- ▼ Call Stack
  - ▶ addTwoNumbers filename.js:2
  - onclick
  - VM77 debugging.html:7
- ▼ Scope
  - ▼ Local
    - ▶ this: Window
    - var1: 2
    - var2: 4
  - ▶ Global Window

A blue callout box with the text "Local variables" points to the local scope in the debugger sidebar.

# JavaScript: Variable Scope

- A variable can either be global or local
  - **Global variable** can be referenced from anywhere in the script
  - **Local variable** only exists with the function in which it is declared

The screenshot displays a JavaScript debugger interface. The main editor shows the following code:

```
1 var total = 50;
2 function addTwoNumbers(var1, var2){ var1 = 2, var2 = 4
3 return var3 = var1+var2;
4 }
```

A breakpoint is set at line 3. The right-hand sidebar shows the following information:

- Paused on breakpoint**
- Watch**: total: 50
- Call Stack**: addTwoNumbers filename.js:3, onclick VM98 debugging.html:7
- Scope**:
  - Local**: this: Window, var1: 2, var2: 4
  - Global**: Window
    - PERSISTENT: 1
    - TEMPORARY: 0
    - addEventListener: f addEve...
    - addTwoNumbers: f addTwoNum...
    - alert: f alert()
    - applicationCache: Applicat...
    - atob: f atob()

The bottom-left pane shows the current object's properties, including `total: 50`. A blue callout box points to the Global scope in the right sidebar with the text: "Global variables Vertical Scroll down to see total".

Line 3, Column 3 Coverage: n/a

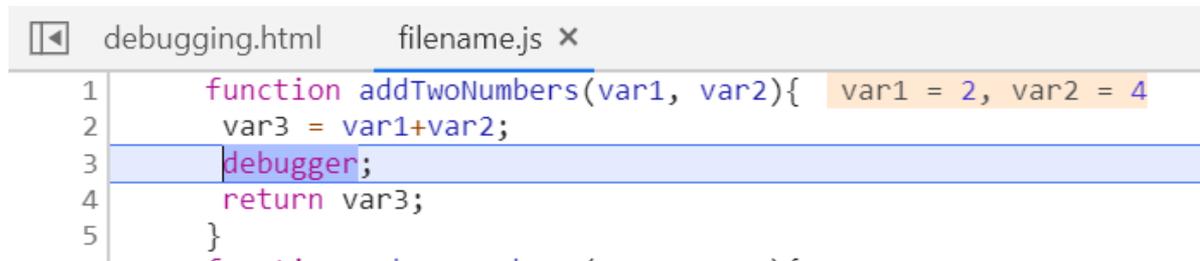

# JavaScript: Variable Scope

- myVar on line 2 is a global variable
- myVar on line 5 is a local variable
- Notice line 9 will use the global variable value since it is in scope

```
01 <script>
02   var myVar = 1;
03   function writeIt(){
04     var myVar = 2;
05     document.write(myVar);
06     writeMore();
07   }
08   function writeMore(){
09     document.write(myVar);
10   }
11 </script>
```

# JavaScript: Log and line of code Breakpoint

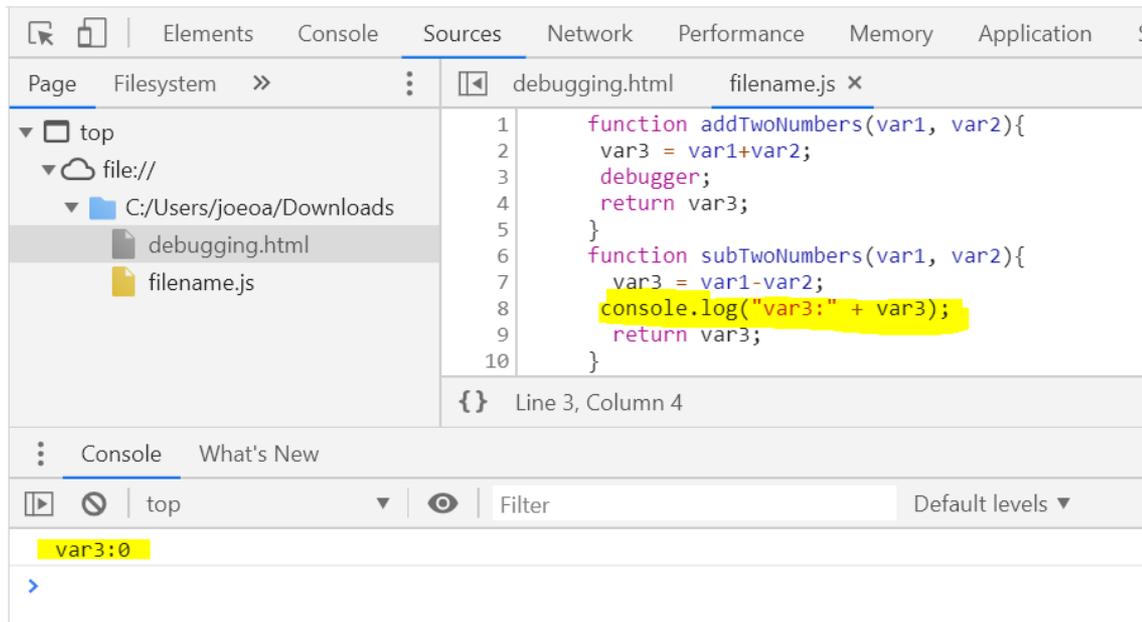

- debugger allows you set in the code where the breakpoint will be hit
- console.log() allows you write to the console area as the code is executing

A screenshot of a code editor showing a JavaScript function. The function is named `addTwoNumbers` and takes two arguments, `var1` and `var2`. The code is as follows:

```
1 function addTwoNumbers(var1, var2){ var1 = 2, var2 = 4
2   var3 = var1+var2;
3   debugger;
4   return var3;
5 }
```

The line `debugger;` on line 3 is highlighted with a blue background, indicating a breakpoint. The variables `var1 = 2, var2 = 4` are highlighted in orange on line 1.

A screenshot of a browser's developer console. The top part shows the 'Sources' tab with the same JavaScript code as the previous image. The breakpoint is set on line 3, and the current execution position is at Line 3, Column 4. The code is as follows:

```
1 function addTwoNumbers(var1, var2){
2   var3 = var1+var2;
3   debugger;
4   return var3;
5 }
6 function subTwoNumbers(var1, var2){
7   var3 = var1-var2;
8   console.log("var3:" + var3);
9   return var3;
10 }
```

The `console.log("var3:" + var3);` line is highlighted in yellow. The bottom part of the console shows the output of the log statement:

```
var3:0
```

# JavaScript: Console Log

- debugger allows you set in the code where the breakpoint will be hit
- console.log() allows you write to the console area as the code is executing

The screenshot displays a web browser's developer console. The top-left pane shows the file explorer with 'debugging.html' and 'filename.js'. The top-right pane shows the JavaScript code with a breakpoint at line 10, column 5. The bottom pane shows the console output, including 'var3:0', the document head structure, and the document body structure.

```
1 function addTwoNumbers(var1, var2){
2   var3 = var1+var2;
3   debugger;
4   return var3;
5 }
6 function subTwoNumbers(var1, var2){
7   var3 = var1-var2;
8   console.clear();
9   console.log("var3:" + var3);
10  console.log(document.head);
11  console.log(document.body);
12  return var3;
13 }
14 function ajax(){
15   var xhr = new XMLHttpRequest();
16   xhr.open('GET', 'https://reqres.in/api/users', true);
17
18   xhr.send();
19 }
```

Line 10, Column 5

  <a id="ajax" onclick="ajax()" href="#test">Ajax request</a>
</body>
```

# JavaScript: AJAX

The `XMLHttpRequest` method `send()` sends the request to the server. If the request is asynchronous (which is the default), this method returns as soon as the request is sent and the result is delivered using events. If the request is synchronous, this method doesn't return until the response has arrived.

```
debugging.html  filename.js x
1  function addTwoNumbers(var1, var2){
2  return var3 = var1+var2;
3  }
4  function subTwoNumbers(var1, var2){
5  return var3 = var1-var2;
6  }
7  function ajax(){
8      var xhr = new XMLHttpRequest();
9      xhr.open('GET', 'https://reqres.in/api/users', true);
10
11     xhr.send();
12
13     xhr.onload = function() {
14         let responseObj = xhr.response;
15         alert(responseObj);
16     };
17 }
```

```
/<!DOCTYPE html>
```

```
<html>
```

```
<head>
```

```
<script type="text/javascript" src="filename.js"></script>
```

```
</head>
```

```
<body>
```

```
  <a id= "add" onclick="addTwoNumbers(2, 4)" href="#test">add two numbers</a><br />
```

```
    <a id= "sub" onclick="subTwoNumbers(4, 4)" href="#test">sub two numbers</a><br />
```

```
    <a id= "ajax" onclick="ajax()" href="#test">Ajax request</a>
```

```
</body>
```

```
</html>
```

```
function addTwoNumbers(var1, var2){
```

```
  return var3 = var1+var2;
```

```
}
```

```
function subTwoNumbers(var1, var2){
```

```
  return var3 = var1-var2;
```

```
}
```

```
function ajax(){
```

```
  var xhr = new XMLHttpRequest();
```

```
  xhr.open('GET', 'https://reqres.in/api/users', true);
```

```
  xhr.send();
```

```
  xhr.onload = function() {
```

```
    let responseObj = xhr.response;
```

```
    alert(responseObj);
```

```
  };
```

```
}
```

HTML for AJAX

JavaScript code for AJAX

# JavaScript: AJAX

- Notice the three xhr methods: open, send, onload

```
1 function addTwoNumbers(var1, var2){
2   return var3 = var1+var2;
3 }
4 function subTwoNumbers(var1, var2){
5   return var3 = var1-var2;
6 }
7 function ajax(){
8   var xhr = new XMLHttpRequest();
9   xhr.open('GET', 'https://reqres.in/api/users', true);
10
11  xhr.send();
12
13  xhr.onload = function() {
14    let responseObj = xhr.response;
15    alert(responseObj);
16  };
17 }
18
```

Paused on breakpoint

- ▶ Watch

  - ▶  DOM Mutation

Line 15, Column 5 Coverage: n/a

Console What's New

```
> xhr.response
{"page":1,"per_page":6,"total":12,"total_pages":2,"data":[{"id":1,"email":"george.bluth@reqres.in","first_name":"George","last_name":"Bluth","avata...
```

# JavaScript: AJAX

- You can set a breakpoint on any XHR or fetch

The screenshot displays a web browser's developer console with a JavaScript file named 'filename.js' open. The code defines three functions: 'addTwoNumbers', 'subTwoNumbers', and 'ajax'. The 'ajax' function uses XMLHttpRequest to send a GET request to 'https://reqres.in/api/users'. A breakpoint is set on the 'xhr.send()' line (line 11). The right-hand sidebar shows the 'Paused on XHR or fetch' status and a list of breakpoint categories, with 'Any XHR or fetch' checked.

```
1 function addTwoNumbers(var1, var2){
2   return var3 = var1+var2;
3 }
4 function subTwoNumbers(var1, var2){
5   return var3 = var1-var2;
6 }
7 function ajax(){
8   var xhr = new XMLHttpRequest(); xhr = XMLHttpRequest {onreadystatechange
9   xhr.open('GET', 'https://reqres.in/api/users', true);
10
11  xhr.send();
12
13  xhr.onload = function() {
14    let responseObj = xhr.response;
15    alert(responseObj);
16  };
17 }
18
```

**Paused on XHR or fetch**  
https://reqres.in/api/users

- ▶ Watch
- ▶ Call Stack
- ▶ Scope
- ▶ Breakpoints
- ▼ XHR/fetch Breakpoints +
  - Any XHR or fetch
  - ▶ DOM Breakpoints
  - ▶ Global Listeners
  - ▼ Event Listener Breakpoints

# JavaScript: AJAX

- You can set a breakpoint on an Event Listener - XHR

The screenshot shows a code editor with the following JavaScript code:

```
1 function addTwoNumbers(var1, var2){
2   return var3 = var1+var2;
3 }
4 function subTwoNumbers(var1, var2){
5   return var3 = var1-var2;
6 }
7 function ajax(){
8   var xhr = new XMLHttpRequest();
9   xhr.open('GET', 'https://reqres.in/api/users', true);
10
11  xhr.send();
12
13  xhr.onload = function() {
14    let responseObj = xhr.response;
15    alert(responseObj);
16  };
17 }
18
```

The code is displayed in a window titled "debugging.html" with a sub-tab "filename.js". The file path is "top/file:///C:/Users/joeoa/Downloads". The status bar at the bottom indicates "Line 14, Column 23" and "Coverage: n/a".

On the right side, the "Event Listener Breakpoints" panel is open, showing a list of event types. The "XHR" event type is selected and expanded, showing the following sub-events:

- readystatechange
- load
- loadstart
- loadend

# JavaScript: Log and line of code Breakpoint

- debugger allows you set in the code where the breakpoint will be hit
- console.log() method allows you write to the console area as the code is executing

```
function addTwoNumbers(var1, var2){  
    var3 = var1+var2;  
    debugger;  
    return var3;  
}  
function subTwoNumbers(var1, var2){  
    var3 = var1-var2;  
    console.log("var3:" + var3);  
    return var3;  
}
```

# JavaScript: Events

- Events
  - Actions that are preformed by a user that can be detected by JavaScript
  - Every element in the DOM has certain events linked to them
  - Examples
    - Mouse click
    - Page or image loading
    - Mouse over
    - Selecting an input field
    - Submitting form
    - Keystroke

# JavaScript: Events

- Events Contd.
  - onLoad and unload
    - Triggered when the user enters or leaves a page
    - Can be used for browser detection and cookies
  - onFocus, onBlur, and onChange
    - Used to validate form fields
  - onSubmit
    - Used to validate all form fields before it is submitted
  - onMouseOver and onMouseOut
    - Used for animations and effects

# Internettechniken

## JavaScript Teil 2 --- AJAX

Prof. Dr. Jürgen Heym

Hochschule Hof

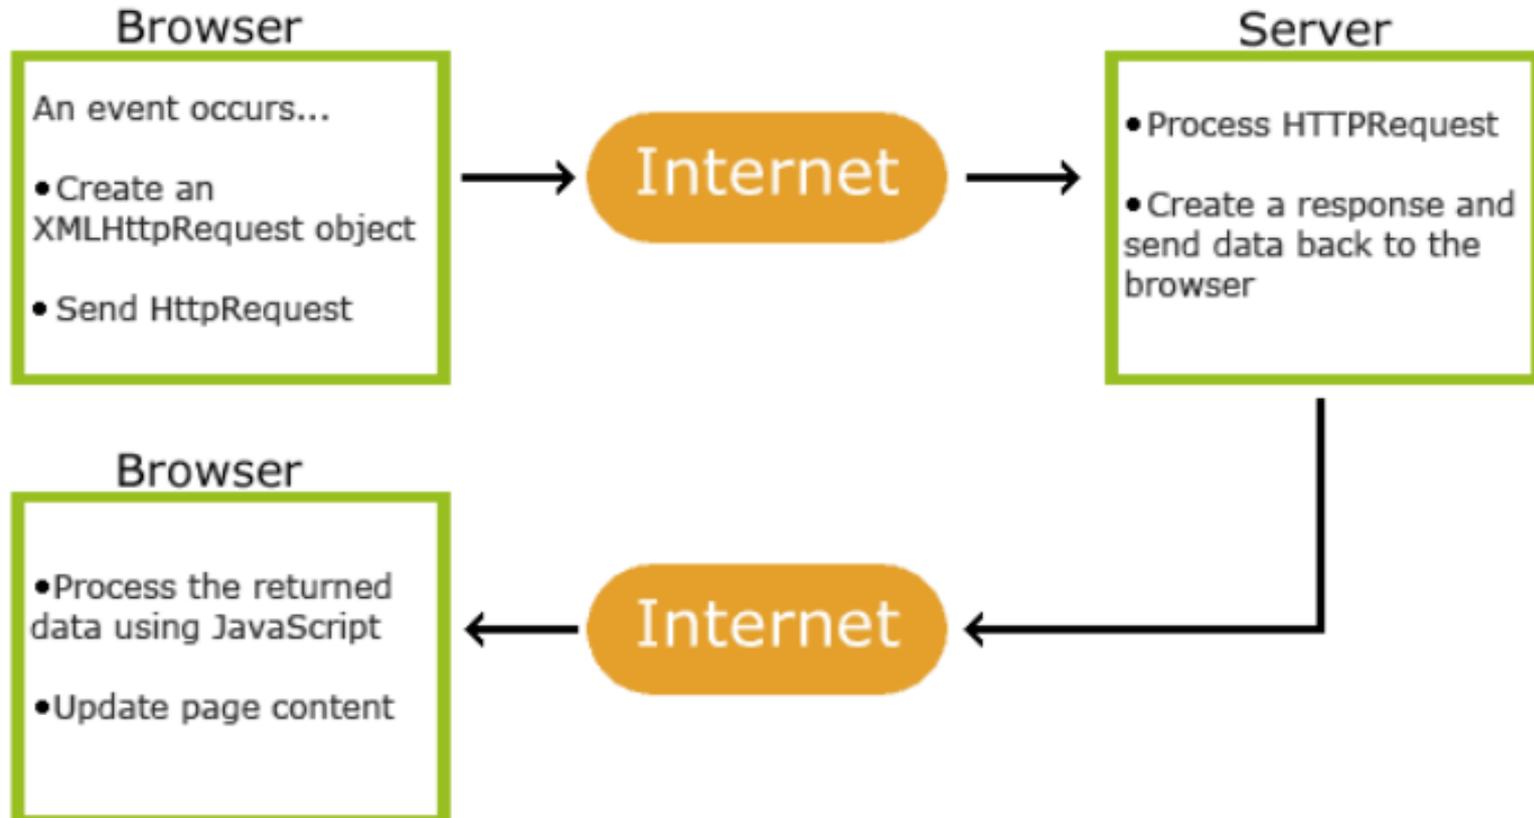

# JavaScript

## Einleitung

- AJAX == Asynchronous JavaScript and XML
- AJAX unterstützt den Datenaustausch mit einem Server und die Teile einer Webseite auszutauschen, ohne die gesamte Seite neu zu laden.
- AJAX ist keine neue Programmiersprache, sondern ein anderer Weg bekannt Standards einzusetzen.
  - XMLHttpRequest Objekt (asynchroner Datenaustausch)
  - JavaScript/DOM
  - CSS
  - XML
- AJAX–Anwendungen sind (meist) unabhängig von Browser und Plattform.

# JavaScript

## Datenflussdiagramm

- Beispielanwendung
  - Das Dokument enthält eine DIV-Sektion, die dynamisch mit Inhalten vom Server gefüllt werden soll, sobald der Knopf aktiviert wird.

```
<html>
```

```
<body>
```

```
<div id="myDiv"><h2>Let AJAX change this text</h2></div>
```

```
<button type="button" onclick="loadXMLDoc()">Change Content</button>
```

```
</body>
```

```
</html>
```

# JavaScript

## Beispiel

- Beispielanwendung --- 2. Schritt
  - Fügen Sie einen JavaScript-Rumpf hinzu.

```
...  
<head>  
<script type="text/javascript">  
    function loadXMLDoc()  
    {  
        //.... AJAX script goes here ...  
    }  
</script>  
</head>  
...
```

# JavaScript

## Beispiel

- Beispielanwendung --- 3. Schritt
  - Wir erzeugen ein XMLHttpRequest-Objekt für den Datenaustausch mit dem Server.

...

```
var xmlhttp;  
if (window.XMLHttpRequest)  
    { // code for IE7+, Firefox, Chrome, Opera, Safari  
      xmlhttp=new XMLHttpRequest();  
    }  
else  
    { // code for IE6, IE5  
      xmlhttp=new ActiveXObject("Microsoft.XMLHTTP");  
    }
```

...

# JavaScript

## Beispiel

- Beispielanwendung --- 4. Schritt
  - Als nächstes nutzen wir die Methoden `open` und `send` des `XMLHttpRequest`-Objekts, um eine Datei nachzuladen.

...

```
xmlhttp.open("GET", "ajax_info.txt", true);
```

```
xmlhttp.send();
```

...

Method	Description
<code>open(method,url,async)</code>	Specifies the type of request, the URL, and if the request should be handled asynchronously or not.  <i>method</i> : the type of request: GET or POST <i>url</i> : the location of the file on the server <i>async</i> : true (asynchronous) or false (synchronous)
<code>send(string)</code>	Sends the request off to the server.  <i>string</i> : Only used for POST requests

# JavaScript

## GET-Request

- Beispiele für GET-Requests

...

```
xmlhttp.open("GET", "demo_get.asp", true);  
xmlhttp.send();
```

...

- Könnte eine Seite aus dem Cache liefern.  
Deswegen fügt meine eine zufällige ID der URL hinzu:

...

```
xmlhttp.open("GET", "demo_get.asp?t=" + Math.random(), true);  
xmlhttp.send();
```

...

# JavaScript

## POST-Request

- POST-Requests sind robuster und sicherer.  
Wir können damit ein Formular „imitieren“.  
Der Header muss in diesem Fall gesetzt werden:

...

```
xmlhttp.open("POST", "ajax_test.asp", true);  
xmlhttp.setRequestHeader("Content-type", "application/x-www-form-urlencoded");  
xmlhttp.send("fname=Henry&lname=Ford");
```

...

Method	Description
<code>setRequestHeader(<i>header</i>,<i>value</i>)</code>	Adds HTTP headers to the request.  <i>header</i> : specifies the header name <i>value</i> : specifies the header value

# JavaScript

## Asynchron --- True oder False?

- Damit wir echtes AJAX nutzen, ist der Parameter „asynchron“ auf den Wert „true“ zu setzen.
- Man muss in diesem Fall eine Funktion definieren, die ausgeführt wird, sobald die Antwort fertig ist.

...

```
xmlhttp.onreadystatechange=function()  
{  
  if (xmlhttp.readyState==4 && xmlhttp.status==200)  
  {  
    document.getElementById("myDiv").innerHTML=xmlhttp.responseText;  
  }  
}  
xmlhttp.open("GET","ajax_info.txt",true);  
xmlhttp.send();
```

...

# JavaScript

## Gesamtes Beispiel ajax-1.html + ajax\_info.txt

```
<html>
<head>
<script type="text/javascript">
function loadXMLDoc()
{
var xmlhttp;
if (window.XMLHttpRequest)
  { // code for IE7+, Firefox, Chrome, Opera, Safari
  xmlhttp=new XMLHttpRequest();
  }
else
  { // code for IE6, IE5
  xmlhttp=new ActiveXObject("Microsoft.XMLHTTP");
  }
xmlhttp.onreadystatechange=function()
  {
  if (xmlhttp.readyState==4 && xmlhttp.status==200)
    {
    document.getElementById("myDiv").innerHTML=xmlhttp.responseText;
    }
  }
xmlhttp.open("GET","ajax_info.txt",true);
xmlhttp.send();
}
</script>
</head>
<body>

<div id="myDiv"><h2>Let AJAX change this text</h2></div>
<button type="button" onclick="loadXMLDoc()">Change Content</button>

</body>
</html>
```

# JavaScript

## HttpResponse

- Server-Antwort als String oder XML
  - Um die Antwort vom Server zu verarbeiten nutzen wir die Eigenschaften `responseText` oder `responseXML` des XHR-Objekts:

Property	Description
<code>responseText</code>	get the response data as a string
<code>responseXML</code>	get the response data as XML data

- Beispiel für `responseText`

```
document.getElementById("myDiv").innerHTML=xmlhttp.responseText;
```

# JavaScript

## responseXML

- Server-Antwort als String oder XML
  - Beispiel für responseXML

```
xmlDoc=xmlhttp.responseXML;  
  
txt="";  
  
x=xmlDoc.getElementsByTagName("ARTIST");  
  
for (i=0;i<x.length;i++){  
    txt=txt + x[i].childNodes[0].nodeValue + "<br />";  
}  
  
document.getElementById("myDiv").innerHTML=txt;
```

- Sobald der Request zum Server geschickt wurde, möchte man Aktionen ausführen, die von der Antwort abhängig sind.
- Das Ereignis “onreadystatechange” wird immer, wenn der Zustand “readyState” sich ändert, ausgelöst.
- Die Eigenschaft “readyState” enthält den Status des XMLHttpRequest.
- Die drei wichtigsten Eigenschaften des XMLHttpRequest-Objekts sind:

Property	Description
onreadystatechange	Stores a function (or the name of a function) to be called automatically each time the readyState property changes
readyState	Holds the status of the XMLHttpRequest. Changes from 0 to 4: 0: request not initialized 1: server connection established 2: request received 3: processing request 4: request finished and response is ready
status	200: "OK" 404: Page not found

- Wir spezifizieren die Funktion, die ausgeführt werden soll, wenn die Antwort des Servers vorliegt:

```
xmlhttp.onreadystatechange=function(  
{  
  if (xmlhttp.readyState==4 && xmlhttp.status==200)  
  {  
    document.getElementById("myDiv").innerHTML=xmlhttp.responseText;  
  }  
}
```

- Sobald man mehrere AJAX-Funktionen nutzen möchte sollte man Callback-Funktionen einsetzen:

```
...  
<script type="text/javascript">  
var xmlhttp;  
function loadXMLDoc(url, cfunc)  
{  
if (window.XMLHttpRequest)  
    {  
        // code for IE7+, Firefox, Chrome, Opera, Safari  
        xmlhttp=new XMLHttpRequest();  
    }  
else  
    {  
        // code for IE6, IE5  
        xmlhttp=new ActiveXObject("Microsoft.XMLHTTP");  
    }  
xmlhttp.onreadystatechange=cfunc;  
xmlhttp.open("GET",url,true);  
xmlhttp.send();  
}  
...
```

- In myFunction wird die soeben definierte Funktion loadXMLDoc genutzt:

...

```
function myFunction1 ()
{
loadXMLDoc ("ajax_info.txt", function ()
    {
    if (xmlhttp.readyState==4 && xmlhttp.status==200)
        {
        document.getElementById ("myDiv").innerHTML=xmlhttp.responseText;
        }
    });
}
</script>
```

...

# JavaScript

## Callback-Funktion

- ... und hier wird myFunction eingesetzt:

...

```
<body>
```

```
<div id="myDiv"><h2>Let AJAX change this text</h2></div>
```

```
<button type="button" onclick="myFunction1 ()>Change Content</button>
```

```
</body>
```

```
</html>
```

# Internettechniken

## JavaScript Teil 3 --- PopUp-Fenster

Prof. Dr. Jürgen Heym

Hochschule Hof

# JavaScript

## PopUp-Fenster mit dem Window-Objekt

- Das JavaScript-Objekt „Window“ repräsentiert ein offenes Fenster in einem Browser (Root-Window, PopUp-Windows, Frames, etc.).
- Das Window-Objekt ist nicht standardisiert, aber alle Browser unterstützen es.
- Das Windows-Objekt hat Eigenschaften (properties) und Methoden (methods).

Property	Description
<a href="#">closed</a>	Returns a Boolean value indicating whether a window has been closed or not
<a href="#">defaultStatus</a>	Sets or returns the default text in the statusbar of a window
<a href="#">document</a>	Returns the Document object for the window ( <a href="#">See Document object</a> )
<a href="#">frames</a>	Returns an array of all the frames (including iframes) in the current window
<a href="#">history</a>	Returns the History object for the window ( <a href="#">See History object</a> )
<a href="#">innerHeight</a>	Sets or returns the the inner height of a window's content area
<a href="#">innerWidth</a>	Sets or returns the the inner width of a window's content area
<a href="#">length</a>	Returns the number of frames (including iframes) in a window
<a href="#">location</a>	Returns the Location object for the window ( <a href="#">See Location object</a> )
<a href="#">name</a>	Sets or returns the name of a window
<a href="#">navigator</a>	Returns the Navigator object for the window ( <a href="#">See Navigator object</a> )
<a href="#">opener</a>	Returns a reference to the window that created the window
<a href="#">outerHeight</a>	Sets or returns the outer height of a window, including toolbars/scrollbars
<a href="#">outerWidth</a>	Sets or returns the outer width of a window, including toolbars/scrollbars
<a href="#">pageXOffset</a>	Returns the pixels the current document has been scrolled (horizontally) from the upper left corner of the window
<a href="#">pageYOffset</a>	Returns the pixels the current document has been scrolled (vertically) from the upper left corner of the window
<a href="#">parent</a>	Returns the parent window of the current window
<a href="#">screen</a>	Returns the Screen object for the window ( <a href="#">See Screen object</a> )
<a href="#">screenLeft</a>	Returns the x coordinate of the window relative to the screen
<a href="#">screenTop</a>	Returns the y coordinate of the window relative to the screen
<a href="#">screenX</a>	Returns the x coordinate of the window relative to the screen
<a href="#">screenY</a>	Returns the y coordinate of the window relative to the screen
<a href="#">self</a>	Returns the current window
<a href="#">status</a>	Sets the text in the statusbar of a window
<a href="#">top</a>	Returns the topmost browser window

# JavaScript

## Methoden des Window-Objekts

Method	Description
<a href="#"><u>alert()</u></a>	Displays an alert box with a message and an OK button
<a href="#"><u>blur()</u></a>	Removes focus from the current window
<a href="#"><u>clearInterval()</u></a>	Clears a timer set with setInterval()
<a href="#"><u>clearTimeout()</u></a>	Clears a timer set with setTimeout()
<a href="#"><u>close()</u></a>	Closes the current window
<a href="#"><u>confirm()</u></a>	Displays a dialog box with a message and an OK and a Cancel button
<a href="#"><u>createPopup()</u></a>	Creates a pop-up window
<a href="#"><u>focus()</u></a>	Sets focus to the current window
<a href="#"><u>moveBy()</u></a>	Moves a window relative to its current position
<a href="#"><u>moveTo()</u></a>	Moves a window to the specified position
<a href="#"><u>open()</u></a>	Opens a new browser window
<a href="#"><u>print()</u></a>	Prints the content of the current window
<a href="#"><u>prompt()</u></a>	Displays a dialog box that prompts the visitor for input
<a href="#"><u>resizeBy()</u></a>	Resizes the window by the specified pixels
<a href="#"><u>resizeTo()</u></a>	Resizes the window to the specified width and height
<a href="#"><u>scroll()</u></a>	
<a href="#"><u>scrollBy()</u></a>	Scrolls the content by the specified number of pixels
<a href="#"><u>scrollTo()</u></a>	Scrolls the content to the specified coordinates
<a href="#"><u>setInterval()</u></a>	Calls a function or evaluates an expression at specified intervals (in milliseconds)
<a href="#"><u>setTimeout()</u></a>	Calls a function or evaluates an expression after a specified number of milliseconds

# JavaScript

## Die Methode `windows.open()`

- Syntax

```
window.open(URL, name, specs, replace)
```

Parameter	Description
URL	Optional. Specifies the URL of the page to open. If no URL is specified, a new window with <code>about:blank</code> is opened
name	Optional. Specifies the target attribute or the name of the window. The following values are supported: <ul style="list-style-type: none"><li>• <code>_blank</code> - URL is loaded into a new window. This is default</li><li>• <code>_parent</code> - URL is loaded into the parent frame</li><li>• <code>_self</code> - URL replaces the current page</li><li>• <code>_top</code> - URL replaces any framesets that may be loaded</li><li>• <code>name</code> - The name of the window</li></ul>
specs	Optional. A comma-separated list of items. The following values are supported:
replace	Optional. Specifies whether the URL creates a new entry or replaces the current entry in the history list. The following values are supported: <ul style="list-style-type: none"><li>• <code>true</code> - URL replaces the current document in the history list</li><li>• <code>false</code> - URL creates a new entry in the history list</li></ul>

# JavaScript

## Die Methode `windows.open()`

- Option specs
  - Komma-separierte Liste folgender Optionen

<code>channelmode=yes no 1 0</code>	Whether or not to display the window in theater mode. Default is no. IE only
<code>directories=yes no 1 0</code>	Whether or not to add directory buttons. Default is yes. IE only
<code>fullscreen=yes no 1 0</code>	Whether or not to display the browser in full-screen mode. Default is no. A window in full-screen mode must also be in theater mode. IE only
<code>height=pixels</code>	The height of the window. Min. value is 100
<code>left=pixels</code>	The left position of the window
<code>location=yes no 1 0</code>	Whether or not to display the address field. Default is yes
<code>menubar=yes no 1 0</code>	Whether or not to display the menu bar. Default is yes
<code>resizable=yes no 1 0</code>	Whether or not the window is resizable. Default is yes
<code>scrollbars=yes no 1 0</code>	Whether or not to display scroll bars. Default is yes
<code>status=yes no 1 0</code>	Whether or not to add a status bar. Default is yes
<code>titlebar=yes no 1 0</code>	Whether or not to display the title bar. Ignored unless the calling application is an HTML Application or a trusted dialog box. Default is yes
<code>toolbar=yes no 1 0</code>	Whether or not to display the browser toolbar. Default is yes
<code>top=pixels</code>	The top position of the window. IE only
<code>width=pixels</code>	The width of the window. Min. value is 100

# JavaScript

## Die Methode windows.open()

- Beispiel

```
<html>
<head>
<title>Test</title>
<script type="text/javascript">
function FensterOeffnen (Adresse) {

    MeinFenster = window.open(Adresse, "Zweitfenster",
        "width=300,height=400,left=100,top=200"); MeinFenster.focus();

}
</script>
</head>
<body>
<p><a href="datei.htm" onclick="FensterOeffnen(this.href); return
    false">Link mit Fenster</a>
</p>
</body>
</html>
```

# Internettechniken

## JavaScript / AJAX / PHP

Prof. Dr. Jürgen Heym

Hochschule Hof

# JavaScript / AJAX / PHP

## Übersicht

- Aufgabenstellung

Programmieren Sie eine Beispielanwendung, die ein HTML-Eingabefeld für Postleitzahlen (PLZ) und eines für den Ortsnamen realisiert, das folgende Eigenschaften aufweist:

1. Sobald ein weiteres Zeichen in das Eingabefeld PLZ des Formulars eingegeben wird, werden passende Vorschläge für vorhandene Ortsnamen mit dieser PLZ unterbreitet. Maximal jedoch 7 Vorschläge.
2. Jeder Vorschlag soll als Link ausgeführt werden, der bei Betätigung die PLZ und den Ortsnamen in das Formular überträgt. Die Hinweise werden anschließend gelöscht.

### Lösung --- HTML-Formular

```
<html>
<head>
<script src="1-plz.js" type="text/javascript"></script>
</head>
<body>

<h3>Geben Sie bitte ihre Postleitzahl ein:</h3>

<form action="">
PLZ: <input type="text" id="PLZ" onkeyup="showCity(this.value)" /><br />
Ort: <input type="text" id="ORT" />
</form>

</body>
</html>
```

# JavaScript / AJAX / PHP

1-plz.js

Lösung --- AJAX / JavaScript (Variante 1 mit statischer PHP-Abfrage)

Dateinamen: 1-plz.html, 1-plz.js und 1-sucheORT.php

```
function showCity(str) {
    var xmlhttp;

    if (str.length==0) {
        document.forms[0].ORT.value="Ihre Stadt ...";
        return;
    }

    xmlhttp=new XMLHttpRequest();

    xmlhttp.onreadystatechange=function() {
        if (xmlhttp.readyState==4 && xmlhttp.status==200) {
            document.forms[0].ORT.value = xmlhttp.responseText;
        }
    }

    xmlhttp.open("GET","1-sucheORT.php?q="+str,true);
    xmlhttp.send();
}
```

# JavaScript / AJAX / PHP

## 1-sucheORT.php

Lösung --- AJAX / JavaScript (Variante 1 mit statischer PHP-Abfrage)

Dateinamen: 1-plz.html, 1-plz.js und 1-sucheORT.php

```
<?php  
  
echo "1-sucheORT.php ...";  
  
?>
```

# JavaScript / AJAX / PHP

## 2-plz.html

Lösung --- AJAX / JavaScript (Variante 2 mit statischer PHP-Abfrage)

Dateinamen: 2-plz.html, 2-plz.js und 2-sucheORT.php

```
<html>
<head>
<script src= "2-plz.js" type="text/javascript"></script>
</head>
<body>

<h3>Geben Sie bitte ihre Postleitzahl ein:</h3>

<form action="">
<table>
<tr><td>PLZ</td><td><input type="text" name="PLZ" onkeyup="showCity(this.value)"
    /></td></tr>
<tr><td>Ort</td><td><input type="text" name="ORT" /></td></tr>
</table>
</form>
<p>Vorschläge: <span id="txtVorschlag"></span></p>

</body>
</html>
```

# JavaScript / AJAX / PHP

2-plz.js

Lösung --- AJAX / JavaScript (Variante 1 mit statischer PHP-Abfrage)

Dateinamen: 2-plz.html, 2-plz.js und 2-sucheORT.php

```
function showCity(str) {
    var xmlhttp;

    if (str.length==0) {
        document.forms[0].ORT.value="Ihre Stadt ...";
        return;
    } else {
        document.forms[0].ORT.value="";
    }

    xmlhttp=new XMLHttpRequest();

    xmlhttp.onreadystatechange=function() {
        if (xmlhttp.readyState==4 && xmlhttp.status==200) {

            document.getElementById("txtVorschlag").innerHTML=xmlhttp.responseText;
        }
    }

    xmlhttp.open("GET", "2-sucheORT.php?plz="+str, true);
    xmlhttp.send();
}
```

# JavaScript / AJAX / PHP

## 2-plz.html

Lösung --- AJAX / JavaScript (Variante 1 mit statischer PHP-Abfrage)

Dateinamen: 2-plz.html, 2-plz.js und 2-sucheORT.php

```
<?php

$plz = $_GET["plz"];

$out = "<p>";
$out .= "<ul>";
$out .= "<li>";
$out .= "<a href='' onclick='alert(\"Hallo Welt\")';>PLZ = $plz ...</a>";
$out .= "</li>";
$out .= "</ul>";
$out .= "</p>";

echo $out;

?>
```
